

ORIBATID MITES (ACARI: ORIBATIDA) OF VIETNAM - SPECIES DIVERSITY AND DISTRIBUTION CHARACTERISTICS

Vu Quang Manh

*Center for Biodiversity Resources Education & Development (CEBRED),
Hanoi National University of Education*

Abstract. Oribatid mites (Acari: Oribatida) are one of the most numerous and dominant groups of soil inhabitants that play an important role during soil formation and its biological processes. The paper presents a full list of oribatid mites known of Vietnam (excluding Acari: Astigmata) based on the collected and identified species as well as on literature records from 1967 to 2019. Totally, 726 plus one oribatid species belonging to 245 genera, 90 families, and 41 super-families, together with the specimen's data have been recorded in Vietnam. These oribatid mites species are identified and analyzed along with their distributions known according to the eight natural and man-made factors, including (1) natural region, (2) soil type, (3) climate zone caused by elevation above sea level, (4) habitat type, (5) distance to the sea, (6) climate season, (7) soil vertical distribution, and (8) oribatid body size. This will be an important scientific basis for further analysis on the relationship of the formation of oribatid mite complexes under the influence of natural & man-made factors, contributing to sustainable management of soil ecosystem in Vietnam.

Keywords: Oribatid mite Oribatida, fauna, distribution characteristics, natural & man-made factor, Vietnam.

1. Introduction

Oribatid mites (Acari: Oribatida) are small arachnids with body sizes usually ranging from 0.1 - 0.2 to 1.0 - 1.5 millimeters. They are one of the most numerous and dominant groups of soil inhabitants that play an important role during soil formation and its biological processes. Because of their high species diversity and high population density, as well as an essential role in soil ecosystem, oribatid mites have been investigated worldwide (Gilyarov & Krivolutsky 1975, Jun Chen, Dong Liu & Hui-Fu Wang 2010, Beron 2018) [1-3]. Oribatid community structure, particularly their species diversity, population densities and distribution are easily recognized features of soil, and are closely related to natural and anthropogenic conditions, and to environmental changes.

Received May 16, 2020. Revised June 20, 2020. Accepted June 27, 2020.

Studies on oribatid community and its bioindicator's role of agricultural intensification and environmental and climate changes, are conducted extensively throughout the world (Appita, Sanyal, Santra 2004, Bokhorst et al. 2008, Gergocs, Hufnagel 2009) [4-6]. Many oribatid species sequester calcium and other minerals in their thickened cuticle. They disperse bacteria, fungi and parasites, both externally on their body surface, or by feeding, with subsequent survival of spores during passage through their alimentary tracts (Stunkard 1937, Hag 1994, Krivolutsky, Vu, Phan 1997) [7-9].

In 1967 the first study of Vietnam's oribatids was conducted. Thirty-three oribatid species were identified and all new for Vietnam, of which 29 species and 4 genera described new for science (Balogh & Mahunka 1967) [10]. Following this study were the studies conducted by Vu (1980, 1985), and Vu and his collaborators (Vu, Jeleva & Zonev 1985, Nguyen & Vu 1988, Vu & Vuong 1995, Vu & Nguyen 2000, Vu, Ermilov & Dao 2010) [11-17]. Ecological studies of oribatid mite community structure were carried out in several national parks (NP) Xuan Nha (province of Son La), NP Xuan Son (Phu Tho), NP Tam Dao (Vinh Phuc), NP Cuc Phuong (Ninh Binh), NP Ba Vi (Ha Noi), NP Cat Ba (Hai Phong), Moc Chau Plateau (Son La), in uplands and the Delta of the Hong river, NP Ben En (Thanh Hoa), NP Phong Nha - Ke Bang (Quang Binh), as well as in Central and Southern Vietnam (Cao 1988, Vuong 1996, Phan 2003, Dang 2005, Luu 2007, Nguyen Phan 2007, Dao 2011, Nguyen Tien 2012, Ngo 2012, Tran 2013, Do Hoa 2014, Do Duyen 2015, Ha 2015, Lai et al. 2016, Pham 2016, Phan 2019, Vu, Lai & Ha 2019) [18-34].

The knowledge of Vietnam's oribatid fauna has been increasingly expanded, thanks to the contributions of many international scientists, including Rajski, Szudrowicz (1974), Golosova (1983), Jeleva & Vu (1987), Tsonev & Vu (1987), Pavlichenko (1991), Ermilov et al. (2011), Fernandez et al. (2015), Minor, Ermilov & Anikhin (2017), Ermilov & Frolov (2019) [35-43]. Recently, a Russian colleague Sergey G. Ermilov and his collaborators have made an important contribution to the knowledge of Vietnam's oribatid fauna (Ermilov & Anichkin 2014, Ermilov 2015) [44, 45]. However, almost of their oribatid samples have been obtained informally and illegally under the Vietnamese law on biodiversity (Socialist Republic of Vietnam 2008) [46]. Almost all their data on Vietnam's oribatid mites are often careless, inaccurate and incomplete. The administrative maps of the socialist republic of Vietnam in his publications were presented wrongly, lacking islands and the island regions (Ermilov & Anichkin 2014, Ermilov 2015, Minor, Ermilov & Anichkin 2017) [41, 44-45]. Therefore, all data on Vietnam's oribatid mites given by Sergey G. Ermilov and his collaborators absolutely must be revised carefully before using them [47]. Even so, the results obtained indicate that Vietnam's oribatid mite fauna are very diverse (Vu 2007, 2012, 2015, Ermilov 2015, Lai et al. 2016) [45, 48-50]. They are an important scientific base for further studies on the soil oribatid community structure as a biological indicator of changes in the soil ecosystem. It is suggested that the understanding of the oribatid community as well as the soil animal community in general, is an important scientific and practical basis, contributing to the sustainable management of soil environment and organisms.

This paper is a synthesis of all studies on Vietnam's oribatid fauna undertaken in Vietnam from 1967 until 2019, and is based on oribatid specimens obtained throughout

the country. The aim of this study work is to introduce the species diversity of Vietnam's oribatid mite fauna and to analyze its distribution according to the main natural and man-made factors.

2. Content

2.1. Materials and methods

* *Material*

A checklist is based on a review of the entire literature on Vietnam's oribatid mites as far as they have come to our knowledge, and on reexaminations of all available material deposited in Vietnam. Some material was found to be lost. Type materials housed in museums outside Vietnam was not examined for this study. Materials were examined to check the proper generic position of species. Materials were listed to documents the availability of the oribatid collection in Vietnam for further study. In the present paper, a list of oribatid mites of Vietnam (excluding Acari: Astigmata) is introduced based mainly on the collected and identified species and on literature records from 1967 to 2019. However, within a page limit, this article could not list all the references.

* *Study region*

The distribution characteristics of oribatid mites are analyzed according to 8 natural and man-made factors of Vietnam, including (1) natural geographic area, (2) soil type, (3) climate zone causing by elevation above sea level, (4) habitat type, (5) distance to the sea, (6) climate seasons, (7) soil vertical distribution, and (8) body length.

* *Classification and species identification*

The classification and species identification follow mainly to Subias (2020), with consideration and reconciliation according to Gilyarov & Krivolutsky (1975), Balogh J. & Balogh P. (1992), Aoki (1999), Norton & Behan-Pelletier (2009) and Schatz et al. (2011) [1, 51-55].

2.2. Results

In this paper, the most comprehensive list of Vietnam's oribatid mites (excluding Acari: Astigmata) known is presently based mainly on the collected and identified species, and on literature records from 1967 to 2019. In the list of species, including some those cases recorded as sub-species. However, in subsequent analyzes, we temporarily accept these all sub-species as species. Recently, a Russian colleague Sergey G. Ermilov and his collaborators have made a great contribution to the knowledge of Vietnam's oribatid fauna. However, almost all their data on Vietnam's oribatid mites are often presented inaccurate, careless and incomplete, such as natural region, soil type, habitat type, and even administrative places etc. The administrative maps of the socialist republic of Vietnam in their publications were presented wrongly, lacking islands and the island regions (Ermilov & Anichkin 2014, Ermilov 2015, Miror & Ermilov 2015) [44-45, 56]. As thus it is in their recent article, right at the sampling site, has made unacceptable mistakes. Such as, it is stated that Thu Le Zoo Garden is located in Thanh Tri district of Hanoi city. While in fact it is distributed in Ba Dinh District, right in the heart of Hanoi capital (Ermilov & Starý 2018) [57]. Therefore, all

data on Vietnam's oribatid mites given by Sergey G. Ermilov and his collaborators absolutely must be revised carefully before using them (Ermilov et al. 2011, Vu, Nguyen, Vu 2014) [47, 58].

Eight natural geographic areas analyzed are as follows: I. Northwest, II. Northeast, III. Red River Delta, IV. North Central Coast, V. South Central Coast, VI. Central Highlands, VII. Southeast, and VIII. Southwest (Mekong River Delta) (Dao 1978, Vietnam National Environment Agency 2001). Seven soil types are: (1) db. Coastal saline-acid soil, (2) dp. Acid alluvial soil, (3) dm. Neutral alluvial soil, (4) dd. Ferralitic reddish brown soil, (5) dn. Ferralitic brownish soil derived from limestone, (6) ds. Reddish brown soils derived from basic and intermediate magmatic rocks, and dk. (7) Other soils (Vietnam National Institute for Soils and Fertilizers 2002). Climate zone causing by elevation above sea level are grouped into three groups with seven sub-groups: (1) 0-600m a.s.l. Climate zone of dry to humid monsoon on the foot of the mountain area including c1. 0 - 100 m, c2. > 100 - 300 m & c3. > 300 - 600 m; (2) > 600 - 2,600 m a.s.l. Climate zone of humid to moisture monsoon on the mountain including c4. > 600 - 1,000 m, c5. > 1,000 - 1,600 m & c6. > 1,600 - 2,600 m; and (3) c7. > 2,600 m a.s.l. Climate zone of temperate climate on the mountain (Vu, Taillard 1994, Vietnam National Environment Agency 2001). Eight habitat types studied are following: a. Natural forest, b. Human-disturbed and planted forests, c. Scrub and grassland, d. Grassland, e. The mixed garden around the human habitation with woody trees, perennial and annual plants, f. Cultivated land with perennial plants, g. Cultivated land with annual plants, and h. Other lands (Vietnam Ministry of Agricultural and Development 2006). Distance to the sea includes b1. 0 - 300 m. The coastal area directly affected by sea tides, b2. > 300 - 600 m. Coastal area indirectly affected by sea tides, and b3. > 600 m. Coastal areas not influenced by sea tides. The data on this aspect is important but incomplete, so it should be supplemented in the future. Climate seasons are four: X. Spring including January, February and March, H. Summer -April, May and June, T. Autumn - July, August and September, and D. Winter - October, November and December (Vu, Taillard 1994, Vietnam National Environment Agency 2001) [59, 60]. Vertical distributions in soil ecosystem are grouped into six layers: (+1) Substrate layer above the forest litter or topsoil, (0) Forest litter lying on topsoil, (-1) Topsoil layer 0 - 10 cm, (-2) Soil layer > 10 - 20 cm, (-3) Soil layer > 20 - 30 cm, and (-4) Soil layer > 30 - 40 cm. According to body length, oribatid mites are classified into four groups: n. < 0.250 mm, t. 0.250 - 0.550 mm, l. > 0.550 - 0.850 mm, and r. > 0.850 mm (Table 1).

In total, 726 plus one oribatid species belonging to 245 genera, 90 families and 41 super-families have been recorded in Vietnam. This oribatid mites species recorded are presented along with their known distributions according to the eight key natural and man-made factors, including (1) natural region, (2) soil type, (3) Climate zone caused by elevation above sea level, (4) habitat type, (5) distance to the sea, (6) climate season, (7) soil vertical distribution, and (8) oribatid body size. This will be an important scientific and basicai data for further analysis on the relationship of the formation of oribalid mite complexes under the influence of natural & man-made factors, contributing to sustainable management of soil ecosystem in Vietnam.

Table 1. List of Vietnam's oribatid mite species along with their distributions known

Total: 41 Super-Families, 90 families, 245 genera, 726 plus one species (and sub-species).								

Legends:

Natural geographic areas (1) natural geographic areas analyzed are as follows: I. Northwest, II. Northeast, III. Red River Delta, IV. North Central Coast, V. South Central Coast, VI. Central Highlands, VII. Southeast, and VIII. Southwest (Mekong River Delta).

Soil types: (1) db. Coastal saline-acid soil, (2) dp. Acid alluvial soil, (3) dm. Neutral alluvial soil, (4) dd. Ferralitic reddish brown soil, (5) dn. Ferralitic brownish soil derived from limestone, (6) ds. Reddish brown soils derived from basic and intermediate magmatic rocks, and dk. (7) Other soils.

Climate zones a.s.l: (1) 0-600m a.s.l. Climate zone of dry to humid monsoon on the foot of the mountain area including: c1. 0-100m, c2. >100-300m & c3. >300-600m; (2) >600-2,600m a.s.l. Climate zone of humid to moisture monsoon on the mountain including: c4. >600-1,000m, c5. >1,000-1,600m & c6. >1,600-2,600m; and (3) c7. >2,600m a.s.l. Climate zone of temperate climate on the mountain.

Habitat types: a. Natural forest, b. Human-disturbed and planted forests, c. Scrub and grassland, d. Grassland, e. Mixed garden around the around the human habitation with woody trees, perennial and annual plants, f. Cultivated land with perennial plants, g. Cultivated land with annual plants, and h. Other lands.

Distance to the sea: b1. 0-300m. Coastal area directly affected by sea tides, b2. >300-600m. Coastal area indirectly affected by sea tides, and b3. >600m. Coastal areas not influenced by sea tides.

Climate seasons: X. Spring including January, February and March, H. Summer - April, May and June, T. Autumn -July, August and September, and D. Winter -October, November and December.

Soil vertical layers: (+1) Substrate layer above the forest litter or topsoil, (0) Forest litter lying on topsoil, (-1) Topsoil layer 0-10cm, (-2) Soil layer >10-20cm, (-3) Soil layer >20-30cm, and (-4) Soil layer >30-40cm.

Body length: n. <0,250mm, t. 0,250-0,550mm, l. >0,550-0,850mm, and r. >0,850mm.

Acknowledgements. The author would like to thank the valuable contribution of all his colleagues and students, especially Dao Duy Trinh, Nguyen Hai Tien, Lai Thu Hien, Ha Tra My and Phan Thi Thu Hien in development of this list of Vietnamese oribatid mites (Acaria: Oribatida).
